TEAM LEADER EXAMINATION  
SUPPORT AND SALES

**AUSTRALIA**

**PATENTS ACT 1990**

**PROVISIONAL SPECIFICATION**

***FOR THE INVENTION ENTITLED:-***

**"INTEGRATED PRE-FILTRATION/REVERSE OSMOSIS WATER OPTIMIZATION  
PROCESS"**

**The invention is described in the following statement:-**

### **Field of the Invention**

The invention relates to a method and apparatus for the production of pure or potable water from impure water, brackish water or seawater. More particularly, the method and apparatus relate to the use of micro-filtration and/or ultrafiltration in combination with reverse osmosis.

### **Background of the Invention**

Many methods and devices are known in the prior art for producing drinking water from contaminated water or seawater.

Such prior art devices typically include a form of pre-filter, such as an ultrafiltration (UF) or micro-filtration (MF) unit or particulate matter pre-filter, in conjunction with a reverse osmosis filter. The pre-filter serves to remove particulate matter, such as organic and/or insoluble particulate matter and thus protects the reverse osmosis filter from destruction. The reverse osmosis filter acts to remove ionic components, such as dissolved salts from seawater.

One of the inherent problems in using UF or MF membrane filters to pre-filter water prior to reverse osmosis treatment is that such filters can become clogged with particulate matter. This is especially the case in those systems where the filtrate is extremely impure and/or in large volumes, which is particularly the case where seawater is being filtered. It therefore becomes necessary to clean such filters periodically and the simplest method of doing this is by backwashing the filters. Backwashing involves reversing the flow across the filter to force and solid or particulate matter which has become entrapped in the filter cavities back into suspension. Normally, a portion of the reverse osmosis feedwater, which as already passed through the UF or MF membrane, is used to backwash the membrane filter.

Usually only 50-90% of the reverse osmosis feed actually passes through the reverse osmosis membrane to become desalinated reverse osmosis product, i.e. potable water, so losses to backwashing are acceptable.

It is also known in the prior art to use the residual reverse osmosis feed that does  
5 not pass through the membrane i.e. the reverse osmosis reject or reverse osmosis concentrate as the backwash source for the membrane backwash. This is disclosed, for example in US 6,120,688 where a portion of the reverse osmosis feed is redirected into a CIP (Cleaning In Place) tank which can from time to time be used to provide a flow to a micro-filtration module in a reverse direction to backwash the membranes.

10 However, there is an inherent problem with such an approach, namely that the reverse osmosis concentrate can form scales or particles due to the concentration effects of the reverse osmosis process. Alternatively, it is possible that there is biological growth on the reverse osmosis membrane surface which can likewise contaminate the reverse osmosis concentrate. Such particles or biological material could in fact foul the  
15 clean or filtrate side of the micro-filtration or ultrafiltration membranes of residual reverse osmosis feed is used directly to backwash the micro-filtration or ultrafiltration membranes.

It is an object of the present invention to overcome or ameliorate at least one of the disadvantages of the prior art, or to provide a useful alternative.

20 Any discussion of the prior art throughout the specification should in no way be considered as an admission that such prior art is widely known or forms part of common general knowledge in the field.

### Summary of the Invention

Accordingly, in a first aspect, the present invention provides a method of purifying impure water contaminated with a filterable impurity and a dissolved impurity, the method comprising the steps of:

- 5 providing impure water to a primary microfiltration or ultrafiltration unit to remove the filterable impurity and produce impure filtered water contaminated with a dissolved impurity;
- providing the impure filtered water contaminated with a dissolved impurity to a reverse osmosis unit to produce a potable water stream and a residual reverse osmosis stream;
- 10 and
- treating the residual reverse osmosis stream prior to reuse.

As used herein, "insoluble impurities" include those typically found in sea water and other natural bodies of water, and include organic and inorganic matter, particulate matter, biological and non-biological matter etc. The term "dissolved impurities"

15 includes for example, dissolved, soluble or solubilized organic or inorganic matter. Most typically, of course, in seawater the greatest quantity of these will be sodium ions and chloride ions.

The term "comprising" is used in an inclusive sense, i.e. "including", rather than in an exclusive sense, i.e. "consisting of".

- 20 In one particularly preferred embodiment, the residual reverse osmosis stream is used to backwash the microfiltration or ultrafiltration unit.

It is also preferred if the residual reverse osmosis stream is treated prior to being reused by being passed through a secondary microfiltration or ultrafiltration membrane.

The residual reverse osmosis stream may be treated prior to being reused, in addition to, or as an alternative to, being passed through a secondary microfiltration or ultrafiltration membrane, by one or any combination of the following treatments:

- Chemical treatment, for example chlorination, fluorination, disinfection, scale control treatment, water softening (i.e. with lime), peroxide, sulfite/bisulfite, ozone or the like.

- Radiation treatment, for example, UV, IR, microwave

- Physical treatment, for example, ultrasonication or vortexing,

- Other treatments, such as heat, electroprecipitation, magnetic treatments etc.

Most preferably, the residual reverse osmosis feed is used to backwash the primary microfiltration or ultrafiltration unit but is subject to ultrafiltration or microfiltration by a secondary ultrafiltration or microfiltration unit prior to said backwashing.

In a particularly preferred embodiment, the invention provides a method of purifying impure water, the method comprising the steps of providing a primary microfiltration unit, a reverse osmosis unit, and means for directing residual reverse osmosis feed to backwash said microfiltration unit and wherein the residual reverse osmosis feed is further subjected to ultrafiltration or microfiltration by a secondary ultrafiltration or microfiltration unit prior to a step of backwashing the primary ultrafiltration or microfiltration membrane.

In another aspect, the invention provides apparatus for purifying impure water contaminated with a filterable impurity and a dissolved impurity, the apparatus comprising:

- a primary microfiltration or ultrafiltration unit to remove the filterable impurity;
- a reverse osmosis unit to produce a potable water stream and a residual reverse osmosis stream;

a conduit to transfer impure filtered water contaminated with a dissolved impurity from the primary microfiltration or ultrafiltration unit to the reverse osmosis unit; and means for treating the residual reverse osmosis stream prior to reuse.

In one preferred embodiment, the residual reverse osmosis stream is directed by a  
5 conduit to backwash the primary microfiltration or ultrafiltration unit.

In a particularly preferred embodiment, the residual reverse osmosis stream is directed by a conduit through a secondary microfiltration or ultrafiltration membrane to backwash the primary microfiltration or ultrafiltration unit.

The apparatus may also include, in addition or alternatively to the above secondary  
10 microfiltration or ultrafiltration membrane, one or any combination of the following:

- Ports for the introduction of chemical agents such as chlorination agents, fluorination agents, disinfecting agents, scale control treatment agents, water softening agents (i.e. with lime), peroxide, sulfite/bisulfite, or the like;
- Ports for the introduction of treatment gases, such as chlorine or ozone
- 15 • Irradiation means such as UV light, IR, microwave sources
- Ultrasonic generators, vortexing devices, heating elements, electroprecipitators, magnetics etc.

Thus, in another preferred aspect, the invention provides apparatus for purifying impure water contaminated with a filterable impurity and a dissolved impurity, the  
20 apparatus comprising:

a primary microfiltration or ultrafiltration unit to remove the filterable impurity;  
a reverse osmosis unit to produce a potable water stream and a residual reverse osmosis stream;  
a conduit to transfer impure filtered water comprising a dissolved impurity from the  
25 primary microfiltration or ultrafiltration unit to the reverse osmosis unit; and

a conduit to transfer a residual reverse osmosis stream from the reverse osmosis unit to backwash the primary microfiltration or ultrafiltration unit via a secondary microfiltration or ultrafiltration unit.

The present invention also provides a separate backwashable or disposable  
5 cartridge microfiltration or ultrafiltration system for filtering residual reverse osmosis feed that is used for micro-filtration or ultrafiltration backwash in order to prevent particulate fouling of the clean or filtrate side of the micro-filtration or ultrafiltration membrane.

Further, the invention provides in certain desalination applications, a method of  
10 filtration of the residual reverse osmosis feed which requires multiple stages of filtration. Such multiple stages include a first filtration through a coarse filter prior to filtration through a membrane filter and further allow the use of filtered residual reverse osmosis reject to backwash coarse backwashable filters such as single or multimedia filters, disc filters, diatomaceous earth filters, membrane filters, strainers, or screens.

15 Currently, filters used to remove suspended solids from water that is subsequently desalinated, must be oversized in order to provide adequate filtered water necessary to backwash or clean the filter. Using the waste stream from a reverse osmosis desalination process for filter backwash or cleaning allows for the construction of a smaller filtration system since it needs to only satisfy the reverse osmosis feed  
20 requirements.

Further, using reverse osmosis concentrate for filter backwash reduces the overall wastewater volume from the combined filter/reverse osmosis facility. Since less raw water is required to achieve the ultimate treatment objectives. Less suspended solids enter the plant with subsequent cost savings in backwash waste treatment chemicals and  
25 sludge disposal.

In some circumstances where the desalination facility is permitted to discharge reverse osmosis concentrate back into the ocean or other receiving body of water it is usually permitted to allow a certain amount of suspended solids to be included in the wastewater typically 30-50mg per litre. By using reverse osmosis concentrate for backwash of the filters it is possible to achieve direct discharge of the backwash waste with less than the permitted maximum suspended solids concentration. This would as a consequence, provide significant savings in suspended solids disposal costs. Normally, it is necessary to settle solids from the filter backwash, dewater the settled solids to form a sludge cake and transport the sludge cake to a landfill for disposal.

#### 10 Description of the Invention

The invention will now be more particularly described with reference to the drawings. Specifically with reference to Figure 1, Item 1 represents the brine which is to be filtered. The brine is taken in by way of a feeder pump 2, which moves the brine along line 3, through pump 4, along line 5 and through valve 6, which during filtration is open leading the seawater into primary microfiltration or ultrafiltration unit 7. Feeder pump 2 may also include a coarse or pre-filtration device. In primary microfiltration or ultrafiltration unit 7 are housed banks of modules of the type which have hollow fibres. The contaminated water passes along the outer side of the hollow fibres and produces clear water in the lumen of the fibres. The clear filtered water exits the primary micro-filtration or ultrafiltration unit at 9. In normal use, valve 10 is open and valve 11 is shut and the micro-filtered water, which is still saline, passes along line 12 to reverse osmosis unit 13. Reverse osmosis unit 13 desalinates the water and produces a desalinated stream of potable water 14 which can be collected for use. The residual, which includes a concentrated saline solution proceeds along line 15. In normal use valve 16 is shut and

valve 17 is open and the concentrated saline solution moves along line 18 and back to be discharged into the brine.

During backwash mode valve 10 is shut and valve 11 is opened. Likewise valve 16 is open and valve 17 is shut. Thus, the reverse osmosis concentrate is forced along  
5 line 15, where upon it passes through a secondary micro-filtration or ultrafiltration unit 20 to produce a filtered saline solution which exits along line 21, moves through valve 11 and serves to backwash micro-filtration modules 8 because there is a positive pressure at 9 and one also at 5, and because valve 22 is open, the backwashed material which is dislodged from the filtration modules exits along line 23 and is returned to the  
10 brine solution.

It will be appreciated that when the material is operating in backwash mode, a source of pressure will be required to force the filtered concentrate back through the primary and secondary micro-filtration or ultrafiltration membrane modules for backwashing. This can be carried out in many ways. Reverse osmosis reject is often  
15 generally available at elevated pressures, and if this is the case, no additional separate pumping source is needed to deliver the reversed osmosis reject at a suitable pressure to backwash the membrane. However, if the reverse osmosis reject is not available at sufficient pressure to backwash the membrane, it may be supplemented, by way of, for preference, a reservoir and pump located along line 21. In this regard, the filtered saline  
20 solution is allowed to accumulate in a CIP tank. The presence of a further reservoir and pump along line 12 will allow the reverse osmosis unit to operate in a continuous fashion.

A further filter can be incorporated either in line 23 to catch the material produced by backwashing, which can be concentrated down to a much smaller volume of water  
25 for sludge disposal.

By following this process, suspended materials which accumulate on the saline side of the reverse osmosis process (the reverse osmosis reject) are prevented from ever contacting the filtration side of the primary ultrafiltration membranes. Secondary micro-filtration or ultrafiltration unit 20 can also have an additional unit for cleaning by  
5 backwashing. This could be cleaned by way of a separate reservoir along line 21 which could be reserved and the contaminate flushed out back along line 16, 17 and 18 and out to waste.

The use of reverse osmosis reject for backwashing has further benefits. The difference in salinity between the feed to the primary microfiltration or ultrafiltration  
10 membrane and the reverse osmosis reject, which has a much higher concentration of ionic species provides an osmotic shock effect that can kill bacteria growing on the microfiltration or ultrafiltration membrane.

Further, in preferred embodiments, acidic components or scale dispersants are added to the reverse osmosis feed, but subsequent to prefiltration in order to prevent  
15 scale precipitation in the reverse osmosis membrane. Thus, in this way, the reverse osmosis concentrate has a lower scale formation potential than the reverse osmosis feed.

Additionally, other benefits may also be realised. The apparatus of the present invention may be fitted with a conventional sand based prefilters to screen out large particles which may damage the primary microfiltration or ultrafiltration membranes  
20 (such as small parts of crustacean shells). The sand in such prefilters often acts as a support for the growth of algae and other micro-organisms. Because of this, the feed water into the primary microfiltration or ultrafiltration units, or at the very least the backwash for the sand prefilters, has typically needed to be chlorinated, to kill algae and other micro-organisms dislodged from the sand. In the present invention, because the  
25 backwash quality is high, it can be used as freely as desired to wash the primary

microfiltration or ultrafiltration membranes. Thus, by the further addition of bactericidal agents, such as chlorine to the reverse osmosis reject at any point, in conjunction (additively or more preferably synergistically) with the osmotic shock effect caused, very high bacterial kills and resultant low bacterial content of the system can be

5 registered without the need to chlorinate large volumes of intake seawater.
